Notes

Asia/London Consolidation→ New York Manipulation & Expansion | Power of 3/AMD/Classic Buy Day

Equilibrium

(Premium/Discount): Basically shows when price overbought or oversold you wanna sell in a premium and buy in a discount.

Application: In LTF and your in a range you ONLY want to enter if price is on or has balanced the side that aligns with your bais. In HTF you want to use it on the daily candle for building a bais and not range wise but AMD wise with the open of the candle being EQ meaning you want it to manipulate the opposite direction in order to trade.(AMD application of EQ can also be applied to 1hr TF)

Liquidity & Imbalances

Liquidity: In basic terms its highs and lows and its important because big money go there to fakeout other traders to take the opposite side of big moneys orders so they can get a better fill.

Imbalances:

- YOU should first be looking for Imbalances and then Liquidity.
  -FVG's: ICT wise the market only moves to fill imbalances or to take liquidity. So if the market only goes to fill an imbalance than its not going to go to price action thats already balanced. If there is an imbalance that price would need to invalidate other building blocks than its not only unprobable but makes it a low probability trade because it disrespected other building blocks that supported your bais.
- NWOG/NDOG:These Gaps form from 5pm-6pm Now that you know price likes to balance out FVG's cause they were only traded one direction then what a strong of a draw do you think straight up gaps have since they weren't traded whatsoever. (use it more as a DOL,NWOG happen Friday 5pm- Sunday 6pm)
- Price Voids: Same as NDOG but not fixed to a certain time.
- NWOG/NDOG:These Gaps form from 5pm-6pm Now that you know price likes to balance out FVG's cause they were only traded one direction then what a strong of a draw do you think straight up gaps have since they weren't traded whatsoever. (use it more as a DOL,NWOG happen Friday 5pm- Sunday 6pm)
- Price Voids: Same as NDOG but not fixed to a certain time.

Fundamentals of Time

Killzones:

- For futures its 8:30am-11:00 am and 7:00am-10:00am for FX These times are when price is most volitile.

Macros

- Last 10mins and first 10min of every hour(9:50am-10:10am is a key one). These times are important because that when price tends to aggressively fill an imbalance or take liquidity and delivers to its objective.
- Hourly Opens
- Basically EQ, you want price to manipulate in the opposite direction of your bias because then you'll have a better entry because price is in discaunt/premium depending on your bais.

Application: Only trade within within macro thats within killzone that is in premium of its hourly candel for sells and discount for buys.

Best PD Arrays

Fair Value Gaps

Inverse Fair Value Gaps
-IFVG's are FVG's that have been traded through so it acts the same as a FVG but in the opposite direction. Its not only an entry but also a confirmation, you could enter at an IFVG but you can also treat it like a BOS cause it broke through a FVG.(side note: although you wouldnt want to enter in discount for short with imbalnces also being in premium, ask yourself does it make sense for price to violate already balanced out PA just to get the imbalance thats in premium.

BPR(Balnaced Price Range)

- FVG the has been inversed by another FVG. Price tends to violate a balanced PA just to get a BPR which is a testament to how strong they are.

Orderblocks
-The last series of down candels before a move up and vice versa. Conceptually OB's hold cause its and area where ppl that were in DD enter their sell orders to close breakeven. The highest probability OB's are the ones that form after a LS or tapping a PD array(their orders is mitigated). OB's hold price its not a DOL

Breaker Blocks

- Inversed OB's
  (if price passes the mid point of an OB and a BB then it becomes way lower probability)

Application: None of these are valid by themeselves so you have to have context and IFVG's,OB's, & BB's hold price not draw it. Pair your SL's with these PD arrays.

How to find Draw on Liquidity

REH & REL
•Realative Equal Highs/Lows tend to be a strong DOL since its just an upsurd amount of stops and the DOL is even stronger when its exact eqaul highs/lows.(Price always takes out exact equal highs/lows)

Low Resistance vs High Resistence
•Low Resistance LIquidity is highs/lows that havent taken any liquidity while High Resistance Liquidity is highs/lows the swept liquidity. You want to trade from HRL to LRL(Basically its area with unfilled orders vs areas that had orders filled, which do you think will attract price)

Internal vs External
•External is high/lows while Internal is FVG's which is supported by the fact that the market only moves to take liquidity or to fill an imbalance.

Previous session highs & lows(I dont really trade asian and lunch)
•Previous day H & L
-If you are below previous day EQ you should be looking to long and short if your above the EQ but once price gets to the EQ of the previous day EQ range then you can assume the DOL is the high/low(PDH if it crosses the EQ of premium range and PDL if it crosses the EQ of discount range)
•London session H & L(12:00am-8:30am)
-Market likes to take out previous session liquidity which is perfect for me cause I can target and trade it.
•Asian session H & L
•AM session H & L
•Lunch Session H & L

- Not every day will have all these DOL's align so the way you find DOL is by wieghing out which side has more of these DOL's.
  •When there is a lot of LRL back to back with DOL lower expect price to aggressively go through them & vice versa.
  • Backtest these DOL's espeacially HRL & LRL and you will become better.

DOL Pt 2

•SMT
-SMT, in the context of Inner Circle Trader's teachings, stands for Smart Money Tool or Smart Money Technique. It involves looking for divergences between closely correlated or inversely correlated assets. By analyzing these relationships between important highs and lows in

correlated markets, traders can gain insights into market movements and potential trading opportunities based on smart money activity.(Is very consistent in its delivery especailly on higher TF's, EVERY big move starts with an SMT and if an SMT forms you can assume price is going higher/lower depending on the type of SMT).

- Disrespected PD Arrays
  -If were bullish we should disrespect bearish PD arrays and respect bullish PD arrays & vice versa(basically OF). If a bearish PD array is disrespected, you can assume the next high is the DOL & vice versa.
- DXY DOL
  -Basically inverse of what you want on NQ. If youre looking to short on NQ you want to see longs on DXY as support and even target the same time in price as DOL. If you see a setup on NQ, you want to see the inverse setup on DXY.

- DOL is either PxL/LRL or an Imbalance
  - OTE or .5 of PD range disrespected to switch bias
  - PA MUST be balanced prior to entry
  - You only feel shakey when you dont give it your all.
  - 1.) Mark PxL/LRL
  - 2.) SMT's
  - 3.) Daily Profile(This hints to which DOL to target)
  - 4.) Wait for Orderflow to align, If not wait for a disrespecte of OTE or .5 to switch bias.
  - 5.) Enter inline with Orderflow

TD Analysis

- Market moves for External & Internal Liquidity.
  -Your finding your DOL on the HTF and as you head down you find things that support it.
- 1M, 1W, & 1D is on sundays.
- 1M: Look at where price is and any PD arrays its tapped into to find DOL
  • 1W: Look for pieces that align with overall DOL
  • 1D: Find pieces that support the 1W
  • 4hr: Find pieces that support the 1D, you also want to see bullish OF
  • 1hr: Look for wather price is going for internal of external liquidity or which stage of AMD its in that aligns with the 4hr
  • 15min: Look at what price is most likely to do that aligns with the 1hr.
  • 1min: You then find an entry point based of the 15min move.

★All your doing is looking at a story, on the 1M it just looks like A→Z but as you go to lower TF's you start seeing the different parts of the story that connect everything together.(The misconception I had was just because 1D is bullish the the 1min WILL be bullish not knowing I skipped the TF's that connected the 1D to the 1min).

- If you're overextended you could expect a retracement to rebalance price prior to going to the DOL.
  • Until you get to your DOL you want to see bullish OF(same if you're bearish).

Orderflow

-OF starts when PD arrays that oppose your direction get disrespected and PD arrays that support your direction form. You would then anticipate PD arrays that support your direction get respected which solidifies the current OF.

-Entries can be made off the retracement to the supporting PD array that first disrespected the opposing PD array or an entry with OF once it's been solidified(basically reversal or continuation entry).

-Having a DOL and then having PD arrays that support that direction be respected and PD arrays that don't support the direction be disrespected.
-Once OF for your direction has started, it must remain in your direction until DOL has been reached.

-If price respects a PD array and displaces from it, it should then have no reason to go back there if DOL isn't booked yet. You can use those respected areas for SL's and look for new entries.

★Price doesn't need to always go to an untapped PD array if there is balanced PA between it and where price is.
★ A disrespected bullish PD array means less in a premium and a disrespected bearish PD array means less in a discount.
★ If your near your DOL and your in line with order flow, with previous PA also being balanced or price would need to change order flow in order to "balance price" which is unlikely if your right about DOL, you can use it to long in premium and short in discount. You dont want to ehter at point where orderflow needs to get disrespected in order to get entered.

★OB's is what you want to focus on as the PD array that gets respected until DOL or a Key level gets tapped.

★Entries should be at points where order flow doesnt need to change in order to get entered or where previous PA is already balanced.

OTE

- Optimum Trade Entry is the .62-.79 retracement tool on the FIB that is marked from a range low to a range high and range high to a range low.
- Pairs really well for a retracement entry after a MSS.
- You don't want to trade purely off of OTE but it gives really good entries when combined with HTF context
  -If you take a trade off OTE you want to at least take partials at range high/low
- If OTE doesn't hold for the range then you can assume the range low/high will be taken.
- You want OTE aligned with some sort of PD array

Standard Deviation

- Use on manipulation legs to project areas where price is likely to head.
  -You can use those areas as targets for price.
- Comes in handy at ATH's/ATL's
  -Trades become higher probability when STDV aligns with some form of liquidity/ PD array.
  -The 2-2.5 projection is a very probable area price tends to respect
  -You can also use it to form a bias by using it on higher TF's to support your DOL or you can trade away from it using it as a form of "support/resistance".
- Standard Deviation means little to nothing if it doesn't align with the DOL.

Daytrading Model

-Within 10am candle because its the open of every single candle from the 4hr and below.(keep in mind every single candle ha a OHLC or OLHC)
-Must enter after 10am
-Max 2 trades a day
-Must have a clear DOL
-Want accumulation/manipulation 10am-10:15am

- Manipulate to PD array/ Key Level
- Long below open and short above open
- Entry model will be order flow
  -Get better at determining the DOL the rest is the easy part.

My model

-Prior to 10:00 i look at where we are at in ERL to IRL(4hr,15min, & 5min) to find the DOL

-If i cant find a clear DOL then no trades

-Once I find the DOL I then look for the lowest hanging fruit price could manipulate to weather it be liquidity or a PD array using OLHC/OHLC

-You then wait for SMT then a IFVG to enter targeting DOL

-You get 2 trades

-No trading after 10:30

Risk Management

-If prop, determine weather your going to trade Futures or CFD's, half the risk on futures.
-Cut risk in half if you lose half your DD
-Max 2 losses a day

- Decide your trade cushion(how many trade losses you know you wont take in a row)

SL/BE/TP

-To know how to place SL you need to understand order flow. When you enter a trade you place the SL at a point where there's no reason for price to go there or where order flow would need to shift.

- You move to BE once there is no reason for price to get back there order flow wise.
- Your TP should be the DOL
- Your SL should be well defended prior to going BE

- Moore doesn't take partials lower than a 2rr. Reason being that he has conviction that the DOL is going to get got so he doesn't want to sell himself short.

✦ You want the first partial to at least make your trade BE even if it hits SL. You can go even further and make the partial the BE point of an adjusted SL.

- Ex.) Take a trade with SL & TP. the partial should be a BE point.
- Ex 2.) Take a trade, adjust SL than make the partial the BE of the adjusted SL. This way lets say price gets to a point of being able to adjust SL but not to the partial, you can then put a closer partial at the BE point of the adjusted SL.

How to build a weekly outlook

★EVERY single weekly either a OLHC or OHLC.

- Just do normal analysis but on 1M,1W, & 1D to find the DOL.
- Once you find the DOL you then align it with OHLC if bearish candle/OLHC if bullish candle, which is basically AMD.
- Mon/Tue is accumulation, Tue/Wed is manipulation, Thur is distribution, & Fri is retracement/TGIV to create the top wick. This is why ICT says lows or high of the week will be Tue or Wed. You can refine the outlook by aligning it with news.
- Once you align each day with news you be able to trade in line with the market.

How to Analyze the Markets

- Do TA on 1M, 1W, & 1D every sunday to see whats most likely goinh to happen theupcoming week.
- Do TA every trading day on 4hr & 15min looking for the DOL. You can do this by marking all forms of DOL for both sides and finding out which one has more.
- Once you find your DOL for the day you then identify orderflow and look to enter in the most logical place possible to where price has no reason to go to SL.

★Focus more on intraday DOL's if PDH/L has already been taken.

How to Properly Study

- Taking notes while watching a long video, then rewatching it to write down key points helps in retaining information. Structuring notes with key points from the video helps in easy revision and understanding concepts.
- Find live several examples when you learn new concepts.
- Note what will help you remember the concept best. Don't write down everything, but what's most important and in your own words.
- Devote as much free time as possible to studying and analyzing price action/backtesting.
- Prioritize spending time studying charts before looking for other learning resources. Utilize weekends and market close times to go through every single day on trading view to gain chart time and practice analyzing trades.
- Utilize all previously taught techniques for analyzing charts and building a bias. Follow a structured study schedule for effective learning, including watching videos with and without notes and finding concepts on charts.
- Structure your day/ have a constant routine, know what your going to do from the moment you wake to the moment you go to bed while accounting for derailers. When you plan what youre going to do the next day visualize it with great detail while tieing emotion to it.
- Structure your environment to be effiecient and require the least amount of willpower as possible because willpower is very potent but very scarce.
- Avoid any form of instant gratification/ stimulation and anything that can cause mental cluttering.
- Success is a result of focused attention channeled into the right areas over time.
- While focus is directed energy, energy comes from sleep, diet, and water so never screw with them.
- High intensity training methods like intervals and static holds are used to train mental toughness. Enduring pain and pushing past mental barriers leads to increased mental toughness for everyday challenges.
- Meditation is about thinking about nothing for 20 minutes. It helps in improving discipline and focus, leading to increased efficiency. Effective in recentering especially when derailing thoughts pop up in times of focus.

- Taking actions in tasks that align with goals & having goals that incompass the characteristics/qualities you want as a person.

How to Master DOL

- Do this on 1hr/15min cause that's where you can see everything clearly.
- Studied in live markets using demo, looking back through old data, or backtesting by categorizing each form of DOL into bullish or bearish.
- Basically go through the DOL's prior to market open marking them bullish or bearish on 1hr/15min then see if your DOL got booked if not, find out why. Your DOL becomes whichever side(bullish/bearish) has more.

★DOL doesnt only mean where price is likely drawn to but also what has price done to support being bullish or bearish.

Quarterly Theory

- Quarterly theory splits the day into four quarters, each with 6 hours, totaling 24 hours.
- Each quarter is further divided into four quarters, representing accumulation, manipulation, distribution, and X.
- True session open in Quarterly Theory is crucial for understanding implied premium or discount. Espeacially midnight and current true open.
- QT should be used as a confluence and not solely by itself, it requres context and be a way to frame your trades.
- When you use QT ask yourself have we accumulated, where have we manipulated, and does is it make sense to have a DOL to where price will ditribute to.
- Basic QT is either XAMD or AMDX and true open is always the start of Q2.
- QT is not always picture perfect and thats why you find your DOL first then see if QT aligns with it and if it does then frame your setup with QT.
- Personally aligning with true open is far more important.

★Basically does the way price distributes align with your DOL.

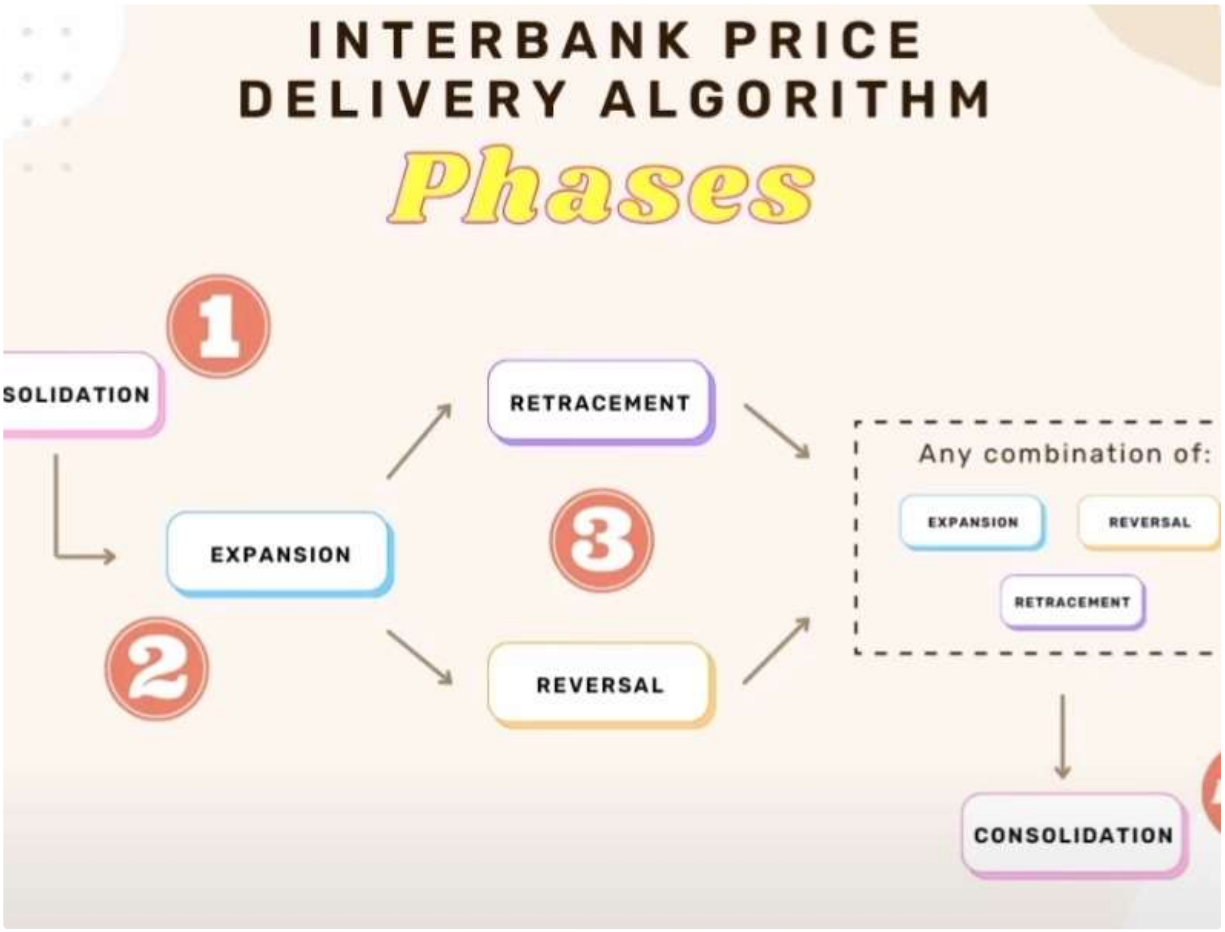

Sweep vs Run

-A sweep is when price takes ERL and fails to displace(FVG) through it while a run is when prce displaces(FVG) through ERL.

-You can use this to see if price is going to revese or continue.

Macros

- Price has 4 moves
  -Consolidation
  -Expansion
  -Reversal
  -Retracement
  -Everything starts with consolidation then expansion→reversal or a retracement→rev,rtrc,or exp→ finally consolidation.

- Macros are the 20min intervals where any of the 4 stages give an oppurntunity to enter.

- Prior to the 9:50 macro is, youll have a specific entry every single time.
  -If you have a reversal at or near 9:30-10:00am you can expect a retracement entry.

-If you have a expansion at or near 9:30-10:00am you can expect a retracement entry.

-If you have a consolidation at or near 9:30-10:00am you can expect a expansion entry.

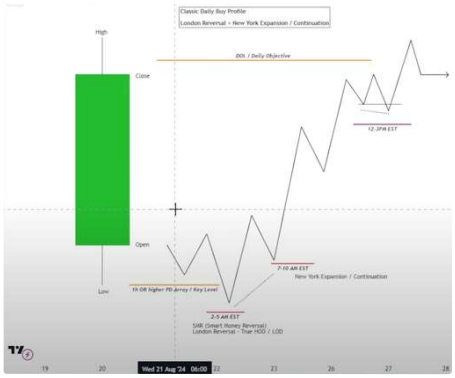

-If you have a retracement at or near 9:30-10:0am it typically means there's news a 10:00am and is lower probability. You have to wait for the news driver in thses type of deliveries.

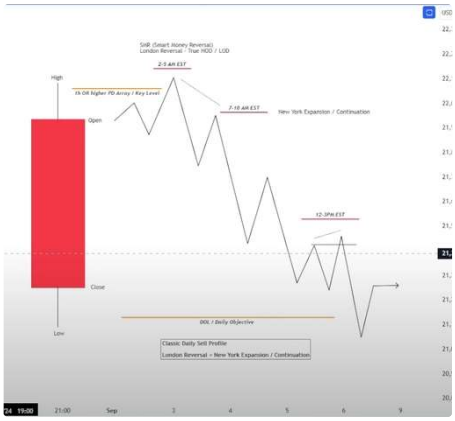

Its Johnny ICT Daily Profile

London Reversal→ New York Expansion/Continuation

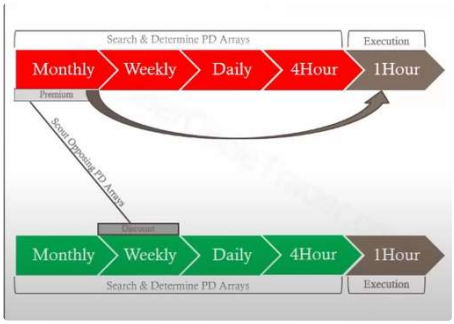

- Classic Daily Buy Profile

- Classic Daily Sell Profile

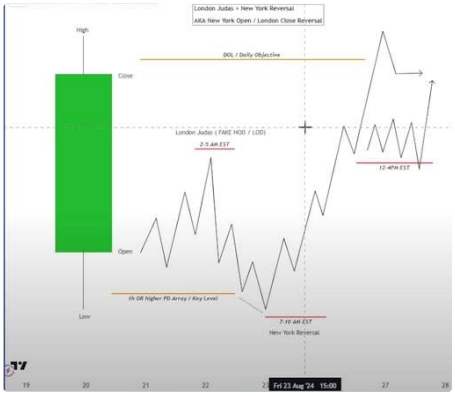

- Sometimes an SMT could form of the reversal point in NY session.
- You want a 1hr or higher PD array to get tapped between 2am-5am to create the LOD/HOD and its confirmed when there is a strong reaction off of it.
- You also want to make sure you get a CISD on the 1hr and NY will be continuation.
- From 12pm-3pm, often times you could get consolidation at EQ of the daily range or right bfore the the DOL gets taken.
- Make sure profile is in alignment with HTF orderflow. Also use TF alignment.

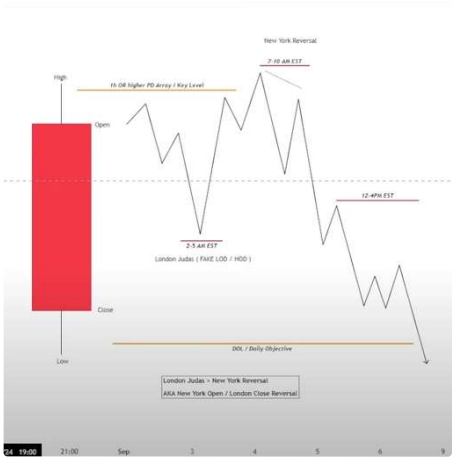

- If youre in a monthly premium you look to trade to a weekly discount and vice versa. But you execute on the lower TF.(4hr P to 1hr D, !hr P to 15min D and vice versa. But 1min execution.)
- You can also apply these profiles to asain session going into London session but it occurs more often on London going into NY.

London Judas→ New York Reversal | New York Open/ London Close Reversal

- London will create a fake HOD/LOD and its confirmed when the London move that occured was without a key level sponsorship for a move into New York meaning the London HOD/LOD didnt tap into and form of PD array on the 1hr or above.

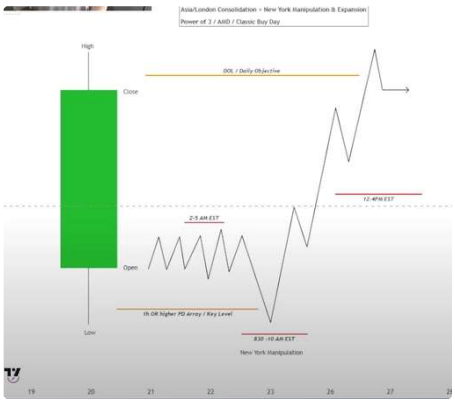

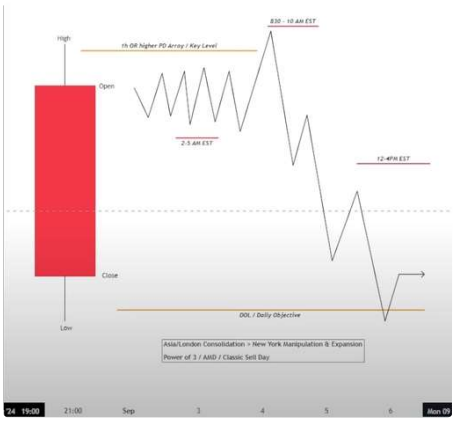

- You will then get the reversal in NY when a 1hr or higher PD array/key level gets tapped around 7am-10am.
- If it fails to take the DOL in the morning session then 12pm-4pm will continue the trend at London close(12pm) or it could consolidate until 4pm to then take the DOL.

Asia/London Consolidation→ New York Manipulation & Expansion

- Usually occurs with 8:30am/10am High Impact News.

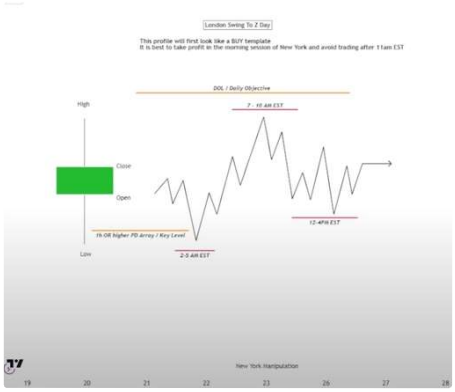

- THERE I NO MANIPULATION WITHOUT AN SMT AND A PD ARRAY/KEY LEVEL GETTING TAPPED.

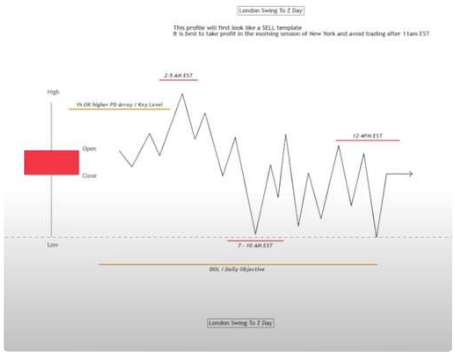

London Swing to Z Day

- This profile at first will look like a Classic Daily Profile and thats why you have to be cautious and why to not trade after 11am.
- Tends to happen on no news days or days after a large expansion.
- 2am-5am will create LOD/HOD and 7am-10am will create HOD/LOD and price will consolidate within that range from 12pm-4pm.

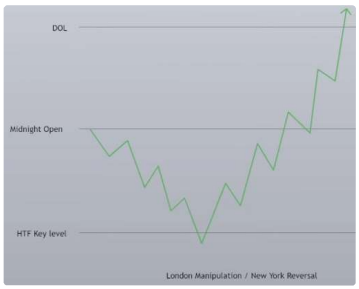

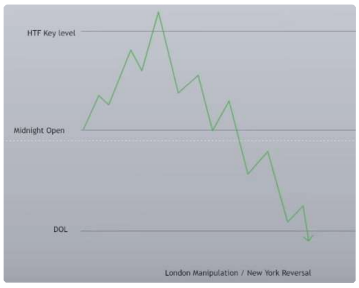

Moore Trades Daily Profiles

London Manipulation/NY Reversal

- During London session you get a manipulation move to a HTF key level leading into NY session(8:30am) then anticipate a reversal towards the DOL. Price should be above midnight open if bearish and below if bullish.

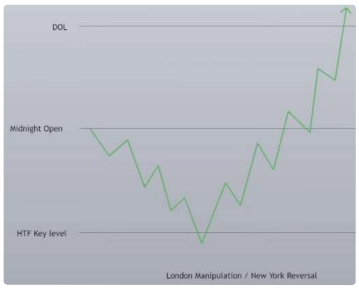

- Expect reversal after NY open.

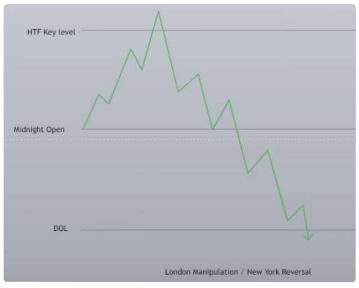

London Reversal/NY Continuation

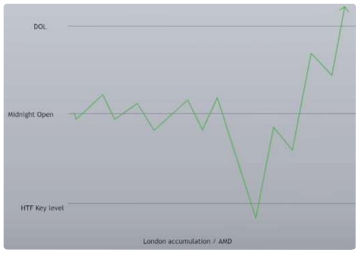

- During London session you manipulate to a HTF key level and while within London session you get a reversal and by the time you get to NY session you should be near or past midnight open.
- Considered London reversal if it occurs anytime before NY open.

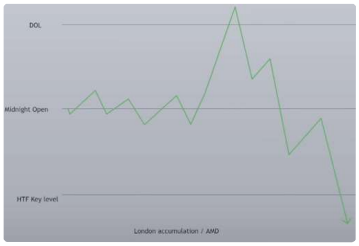

London Accumulation/NY Manipulation & Distribution(AMD)

- London accumulation near/at midnight open, manipulation at NY open then distribution towards DOL.

✧The DOL is typically PxL

✧You should ALWAYS take some form of partial at midnight open.

✧You want to be in when the first entry is offered.(Earliest entry is not always the highest rr one).

✧Typically you want to be in the trade by the time midnight open gets booked.

✧1hr/30min for HTF Key Levels.

✧ PD Array/ Key Level that gets tapped must be outside of the current sessions PA.

✧ If you have a bullish daily profile and you're above midnight open or if you have a bearish daily profile and your below midnight open then you're done for the day .

✧ What makes every single concept high probability is if it tapped/took a HTF PD array/Key Level and it has a DOL.

✧ IFVG's depend on the candle close. If candle closes to far to offer a good RR then you enter on the retracement but if not then you just market order.

✧DOL doesn't usually book before market open but if it does, you then have to be open to the daily profile changing

✧NEED A CLEAR DOL THAT ALIGNS WITH THE DAILY PROFILE.

✧Go to lower TF's to see if imbalances are actually valid

✧When daily profiles set up look for the start of aligning order flow

-He doesn't consider the daily open/Asia session into his daily profiles.

-Unlike Johnny he doesn't limit daily profile to specific times outside of session(0:00-8:30 London, 8:30-11:00 NY am)

Moore Trades How to Find DOL Updated Version

ALL OF THESE IS APPLIED ON THE 15MIN AND ABOVE. ALL OF THESE TOOLS ARE NOT TO BE TAKEN FOR FACE VALUE BUT WITH CONTEXT.

SMT Divergence

- ES & NQ are correlated meaning they move with the same structure and when there is a divergence between the highs or lows it is the market hinting at manipulation and a big move usually follows it. SMT with highs implies bearishness and with lows implies bullishness.

Low Resistance vs High Resistance Liquidity

- REH's/REL's is a form of LRL.
- Basically foundation is built on price delivering efficiently so it doesnt go to highs/lows that already swept liquidity but instead goes to highs/lows that failed to take liquidity resulting in a highe pool of stops being in that area hence why you want to trade towards LRL/REx's.
- Highs/Lows that tap into FVG's are considered HRL. HRL is something that has done what it needs to do and becomes defended.
- DOL should be LRL and you should trade away from HRL

PxL(Most important in Moores opinion)

-Previous Days High/Low

-London Session High/Low

-Asia Session High/Low

-Can also use Data High's/Low's

- Typically when PxL high/low get taken, then the opposing side gets targeted

Other things to mention is pairing these with Order Flow, also using disrespected OTE to change bias.

- You don't want to see CE get closed passed for supporting inefficiencies. Same goes for MTH for blocks
- You ideal entry is also from the midpoint to its high if your bullish and midpoint to is low if your bearish for inefficiencies & blocks.
- ALWAYS look at economic calendar when doing weekly analysis and daily analysis. Not for data purposes but for volume purposes.
- Wicks can be used as points of S/R. Above or Below CE of wicks is the most sensitive area of the wick depending weather your bullish or bearish.
- The first and last 10min of every hour is a macro.
- Turning points are going to be liquidity based or inefficiency based. Entries are always formed on the basis of inefficiencies being retraded to or order blocks being repriced to.
- If you see a lot of down closed candles forming in a buy program, that means either you're at the consolidation midpoint of halfway of that move or you're probably near the high and in the next run it goes up it's going to be the end of it and it's going to collapse. Vice versa for sell program.
- In a buy program OB's in discount are the key things to focus on then focus on IFVG when its in a premium. If in sell program focus on OB's in premium then IFVG's in discount.

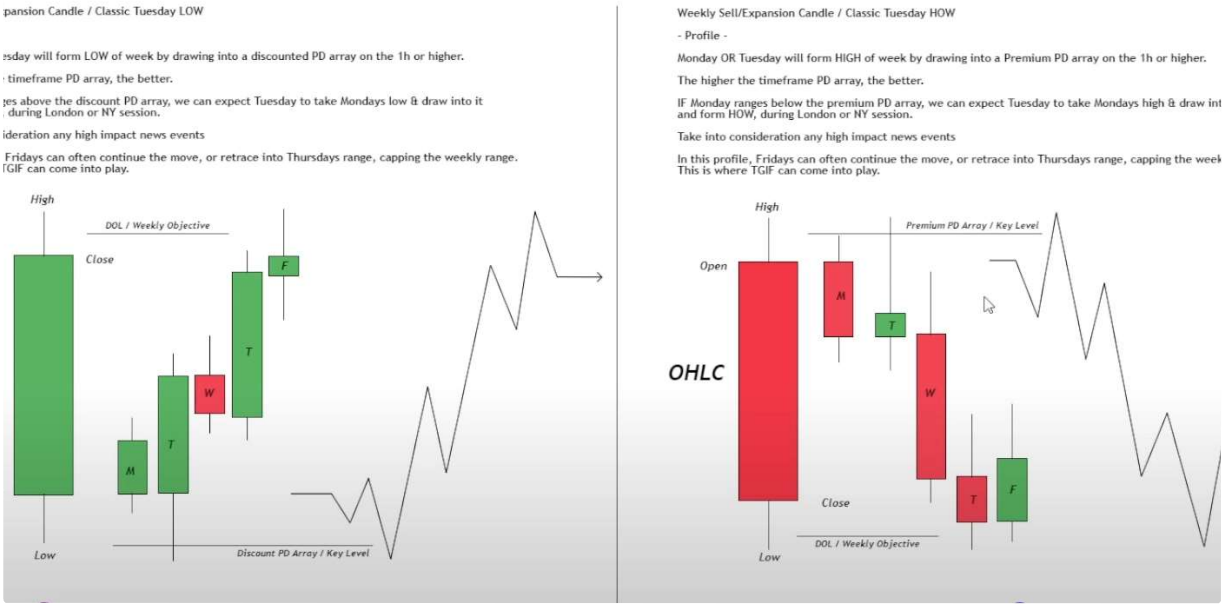

- Transpose Daily lvls to lower TF's. They hold a lot of influence but by themeselves they are not useful, you need to see other things in confluence to support the idea of why price should react a certain way.(1D→1hr, 4hr→15min, 1hr→5min, 30min→1min)
- If there's a change in the state of delivery it's going to seek the opposing side of liquidity or inefficiency.
- If your in a price run, you dont want to see inefficiencies fully filled, if it does then youre likely nearing the end of the price run.
- HTF Order blocks should be qualified based on premium or discount in higher time frames and transposed to lower time frames for analysis. Three PD arrays, including liquidity and specific price levels, are needed to confirm an order block's potential for promoting specific prices.
- The upper portion of an order block from its midpoint to its high and every fair value Gap from its midpoint to its high if you're buying that's your ideal entry. Vice versa if youre selling.
- PD-H's/L's are rich in order flow(have clean moves)
- When ICT says he wants speed through lows/highs its because he's watching how price interacted with the low/high the formed AFTER a MSS. If it diplaces thorough it then he anticipates price to take the actual liquidity pool with speed and pay attention to FVG's, OB's, & VI's(the displacement candle should be a break away gap).
- You want to see price spend very little time in inefficiencies
- BPR are when there is delivery to both sides of the market.
- SL could placed above MTH of wick of first candle on FVG's or at second candles high of BISI or low if SIBI. The reason for this is because it utilizes BPR's which is when there is delivery to both sides of the market.
- FVG's after a consolidation WITH a stop hunt tend to be let open(BAG). You can use these as entries at the start of the FVG or CE. Pay speacial attention to the OB that forms after a BAG, like where it formed and how price interacts with it. (Remember the wick are always allowed to do the damage).

- If the market is going to move it, is going to move to something on the daily chart. All of the things that effect the financial Market are going to derive from the daily chart it's the previous day high and low, the previous day high and low in the last 3 days, last week's high and low the upper quadrant the midpoint and the lower quadrant of that range
- Within a Macro price will either take short term liquidity, trade to an inefficiency, or an OB realative to the time based Premium/Discount to invite smart money to capitalize on an entry right before price spools to the liquidity. EVERY hour a macro is taking place. A macro is like a super charger for efficiency and immediate reaction.
- You know youre onside when price immediately moves away from your entry. You get these entries when you factor in TIME.
- If price displaces through a high/low forming a BB then the displacement FVG is anticipated to be a BAG
- To see the order flow you want pay attention to the OB's and IFVG's and when price gets to EQ of current it tends to make a run on liquidity so don't be so eager to trail SL so tight.
- BAG's are confirmed within the context of where liquidity and inefficiencies lie, what the current structure is, and where price came from(OB's,BB's,FVG's,IFVG's,Liquidity).
- Time Distortion Tends to occur during NY lunch.
- The first FVG after it price starts a run "should be a BAG" espescially if it coming from a consolidation or time distortion.
- Fridays are avoided when the weekly cndle has already had the +20% retracement.
- Using PO3 the ranges retracement will be in the final third of the range.
- If a 1D candle closes without forming the wick then you can expect a retracement the following day.
- Stops lie not just at the high or low but also within the wicks (past the candle close).
- You can use wicks of BB & OB but the bodys are the most sensitive points.
- If an OB entry is left behind and price forms a FVG then you can take the FVG entry cause conceptually a FVG is a DOL while OB's support price

It's Johnny ICT Weekly Profile

- Understand OLHC/OHLC concept.

Weekly Buy/Sell | Expansion Candle | Classic Tue LOW/HOW

- You know its LOW/HOD if 1hr or above PD Array, Key Level, or SMT is sponsoring the move.
- DO NOT PATTERN TRADE THESE WEEKLY PROFILES.

Mid Week Reversal/Wednesday HOW/LOW Reversal
